Allometry of ER with accumulated area.

I think this needs rethinking because area is in both axes

area in both axes - null model is b = slope = 1

Cannot do inference

thus if ER is constant - call it r

$\log(rA) = a + b \log(A)$

it will scale w/ area A as is

$\log(r) + \log(A) = a + b \log A$

$a = r, \quad b = 1$

if r increases with A then $b > 1$

I would instead simply scale r with area

Then you can do inference
